

## PROJECT III (PART B)

Jhonatan Parada

ET574

1. New object attributes created (2). These ones will be used to define the current's player chip 2d coordinates.

```
class Connect4:
    def __init__(self):
        self.board = [[' ' for _ in range(7)] for _ in range(6)]
        self.current_player = 'X'
        self.current_row = None
        self.current_column = None

    def switch_player(self):
```

2. New methods created (3). Set\_coordinates will be a void method, and get\_coordinates will be a non-void method that will return a tuple of the current's player's chip coordinates. The first value will be the row, and the second one will be the column

```
class Connect4:

    def set_coordinates(self, row, column):
        self.current_row = row
        self.current_column = column

    def get_coordinates(self):
        return self.current_row, self.current_column

    def check_win(self, player):
```

3. In the `drop_chip` method, after placing the chip in the board, I will call the `set_coordinates` method and pass it 2 arguments, the coordinate (or index) of the row and column of the cell holding the chip.

```
class Connect4:
    def drop_chip(self, column):
        for row in reversed(self.board):
            if row[column] == ' ':
                row[column] = self.current_player

                # sets the coordinates of current's player chip
                self.set_coordinates(self.board.index(row), column)

                break

        return True

    def play_game(self):
```

4. The `check_win` method uses the first two nested while loops to iterate over the cells surrounding the player's current chip cell. The third and last loop iterates over the chips it encounters that match the same as the current player. The last loop also uses information from the first two loops to calculate the coordinates of a cell in the different 4 alignments that chips can connect.

```
class Connect4:
    def check_win(self, player):
        row, column = self.get_coordinates()
        connect = 4

        i = -1 # i represents the the column
        while i != (1 + 1): # range (-1, 0, 1) for column

            y = -1 # y represents the row
            while y != (1 + 1): # range (-1, 0, 1) for row

                # skips self and upward cell
                if i == 0 and (y == -1 or y == 0): y += 1; continue

                x = 1 # x represents the number of chips that need to be aligned to win the game
                while x != (connect):

                    # Defines the coordinates of a cell after a transition from the current chip
                    new_row = row + (y * x)
                    new_column = column + (i * x)

                    # If either coordinate is negative, that means that the coordinate is out of range
                    if new_row < 0 or new_column < 0: break

                    # checks that the target cell exists and that it is equal to player
                    try:
                        if self.board[new_row][new_column] != player: break
                    except: break

                    x += 1
                else:
                    # getting to this point means that everything went good during the loop
                    # therefore, there a specified number of chips are aligned
                    return True

            y += 1
        i += 1
    return False
```

Let's imagine we have a 5x5 board where the last chip dropped was the one in blue, let's call this chip the original chip, we will look for a connection from this point.

	O		O	
	X	X	O	
	O	O	O	

Let's say that the coordinate of the original chip is (A,B)

Cartesian Plane	Python Syntax
(A, B)	Board[B][A]

Let's say we want to access the cells closer to the left of the original chip (horizontal and diagonal), but how will the code know the coordinate of those cells?

Let's highlight the cells with different colors to see it clearer.

	O		O	
	X	X	O	
	O	O	O	

If

■ = board[B][A]

Then,

■ = board[B - 1][A - 1]

■ = board[B][A - 1]

■ = board[B + 1][A - 1]

Let's express yellow, green and purple in a different way:

 = board[B + (- 1)][A - 1]

 = board[B + (0)][A - 1]

 = board[B + (1)][A - 1]

See the pattern? That's why the sentinels of the first while loops start as -1 and finish as 1 (though they could start as 1 and finish as -1 but we would have to use the -= operator instead of +=) because it will iterate over 3 rows and 3 columns.

Finally, let's imagine this scenario where  was the last chip dropped:

			X	
		X	O	
	X	O	X	
X	O	X	O	

X = board[B][A]

X = board[B + 1][A - 1]

X = board[B + 2][A - 2]

X = board[B + 3][A - 3]

The check\_win method makes use of these two principles to detect every possible connection from the current chip dropped. The method then utilizes if statements to for example skip and not check on the cell above the original cell or that the new cell coordinate is inside the board.

## 5. Winning Diagonally

```
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
-----
1 2 3 4 5 6 7
Player X's turn.
Enter the column number (1-7): 5
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
-----
1 2 3 4 5 6 7
Player X wins!
@jhnatanparada499 →/workspaces/ET574 (main) $
```

## 6. Winning horizontally

```
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
-----
1 2 3 4 5 6 7
Player X's turn.
Enter the column number (1-7): 1
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |
-----
1 2 3 4 5 6 7
Player X wins!
@jhnatanparada499 →/workspaces/ET574 (main) $
```

## 7. Winning Vertically

```

| | | | |
| | | | |
| O | | O |
| O | X | X |
| O | X | O | X |
| X | X | O | O |
-----
 1 2 3 4 5 6 7
Player O's turn.
Enter the column number (1-7): 2
| | | | |
| | | | |
| O | | O |
| O | X | X |
| O | X | O | X |
| X | X | O | O |
-----
 1 2 3 4 5 6 7
Player O wins!
@jhonatanparada499 →/workspaces/ET574 (main) $

```

## 8. Testing main.py with unittest module.

The screenshot shows a code editor with a file named `test_check_win.py` open. The code defines a `Connect4CheckWinTestCase` class that inherits from `unittest.TestCase`. It includes a `setUp` method to initialize a `Connect4` game and three test methods: `test_check_win_horizontal`, `test_check_win_vertical`, and `test_check_win_diagonal`. Each test method sets up a specific sequence of moves and then asserts the state of the game after each move.

```

1 import unittest
2 from main import Connect4
3
4 class Connect4CheckWinTestCase(unittest.TestCase):
5     def setUp(self):
6         self.game = Connect4()
7
8     def test_check_win_horizontal(self):
9         # Test winning horizontally
10        drop_sequence = [4, 4, 3, 3, 2, 2, 5]
11
12        for column in drop_sequence:
13            self.game.drop_chip(column)
14            self.game.switch_player()
15
16        self.assertFalse(self.game.check_win('O'))
17        self.assertTrue(self.game.check_win('X'))
18
19    def test_check_win_vertical(self):
20        # Test winning vertically
21        drop_sequence = [1, 4, 3, 4, 2, 4, 1, 4]
22
23        for column in drop_sequence:
24            self.game.drop_chip(column)
25            self.game.switch_player()
26
27        self.assertFalse(self.game.check_win('X'))
28        self.assertTrue(self.game.check_win('O'))
29
30    def test_check_win_diagonal(self):
31        # Test winning diagonally
32        drop_sequence = [1, 2, 2, 3, 3, 4, 3, 4, 3, 4]
33
34        for column in drop_sequence:
35            self.game.drop_chip(column)
36            self.game.switch_player()
37
38        self.assertFalse(self.game.check_win('O'))
39        self.assertTrue(self.game.check_win('X'))

```

The terminal output shows the command `python projects/Jhonatan_PROJECT3b/test_check_win.py` being executed, which runs 4 tests in 0.000s and outputs "OK".

```

@jhonatanparada499 →/workspaces/ET574 (main) $ python projects/Jhonatan_PROJECT3b/test_check_win.py
....
Ran 4 tests in 0.000s

OK
@jhonatanparada499 →/workspaces/ET574 (main) $

```

Knowing this, let's simplify the `check_win` method:

```

def check_win(self, player):
    row, column = self.get_coordinates()
    indexes = range(-1,1 + 1)
    connect = 4

    for c in indexes:
        for r in indexes:
            if c == 0 and (r == -1 or r == 0): continue
            for i in range(1,connect):
                new_row = row + (r * i)
                new_column = column + (c * i)

                if new_row < 0 or new_column < 0: break
                if new_row > (6 - 1) or new_column > (7 - 1): break
                if self.board[new_row][new_column] != player: break

            else: return True
    return False

```

The if statements behave like filters. C stands for column and r stands for row. We got rid of the try-except statement by checking that the new coordinate is within the limits of the board. The variable indexes can be replaced by a list like [-1,0,1]. The variable connect can be manipulated so instead of playing connect 4 we can be playing connect 3, 5, 6 or even 2. It would not make sense to give the connect variable a number greater than the number of columns or rows of the board.
